⑤④ **Composite helmet.**

⑤⑦ A preform (36) for a protective helmet is made from resin-impregnated blanks cut from a length of reinforcing fabric (10) along a zig-zag line (13) so that each part (14, 15) has a straight edge (11, 12) and a series of teeth (18, 19) defining the opposite edge. Lengths are cut off from each part (14, 15) to form the blanks and are wrapped in a plurality of layers around a cylindrical former, sized to correspond to the head size of the helmet, so that the teeth in successive layers are in staggered relationship. The layers are then compressed in a press (34, 35) to bend the teeth (18) over into mutual engagement and form a rigid domed preform (36).

Composite Helmet

This invention relates to the production of composite helmets. Such helmets are sometimes used by soldiers to provide "ballistic protection" and are then sometimes referred to as "ballistic helmets".

5 Hitherto, composite helmets have been made from strong fabric impregnated with a phenolic resin and cut into a shape called a pinwheel comprising a crown from which radiate a plurality of petals. A number of pinwheels are superposed by placing the crowns of the
10 pinwheels on top of one another so that their petals are in staggered relationship. The preform which results is placed in a heated mould, comprising matched steel dies, in a compression press and is subjected to heat and pressure to form the helmet.

15 In making the pinwheels, much fabric is cut to waste and although the severed pieces of fabric can be built into subsequent preforms, the procedure is labour intensive. The present invention provides a procedure for making composite helmets involving manufacture of
20 a preform from a blank which reduces the amount of wasted fabric.

 According to one aspect of the invention, a method of making a blank for a preform for a composite helmet comprises cutting a length of reinforcing
25 fabric along a zig-zag line so that the length of fabric is dividable along the cutting line into two parts, each part comprising an uncut longitudinally extending base portion and a series of teeth projecting from the said uncut base portion along one edge
30 thereof.

The fabric may be impregnated with a resin

before or after cutting.

The cutting may be carried out by a knife blade on a rotary cutter or by a die cutter.

The fabric may be wound after cutting onto two
5 juxtaposed cylindrical formers having a diameter such that they are approximately the same size as the opening in the helmet to be manufactured. The pitch of the teeth in each part of the cut fabric is advantageously such that when wound on the former, teeth of
10 successive layers of fabric are in staggered relationship.

In making a preform from the cut fabric, one part of the fabric, having been wound on a former to produce a plurality of layers of fabric with
15 overlapping teeth, is shaped by bending the teeth inwardly towards one another so that they meet or overlap at the crown of a helmet shape. The teeth are then joined to one another in the region of the crown, for example by welding, and the preform thus produced
20 is placed in a mould and subjected to heat and pressure to produce a helmet.

The invention includes a composite helmet made from a preform comprising a blank as described above.

The invention will be further described, by way
25 of example, with reference to the accompanying drawing in which:-

Figure 1 shows part of a blank for a preform according to the invention,

- 3 -

- Figure 2 is a diagram illustrating one method of cutting a blank as shown in Figure 1,
Figure 3 illustrates the dividing of the blank of Figure 1 into preform lengths,
5 Figure 4 illustrates a step in the formation of a preform according to the invention,
Figure 5 is a diagram illustrating the final operation in making a preform according to the invention, and
10 Figure 6 is a diagram illustrating the moulding operation to make a helmet from a preform according to the invention.

The blank for a preform according to the invention shown in Figure 1 is a length of fabric 15 10 with straight parallel edges 11 and 12 and, in this case, pre-impregnated with resin. The length of fabric 10 has been cut along a zig-zag line 13 such that the length of fabric can be divided along the line 13 into two parts 14 and 15 each comprising an
20 uncut base portion 16 or 17 adjacent the longitudinal edge 11 or 12 respectively, and a series of identical evenly spaced teeth 18 or 19 projecting from the uncut portion 16 or 17 away from the associated edge 11 or 12.

25 The length of fabric 10 may be cut by intermittent feeding through a die cutter or it may be cut in an apparatus as shown in Figure 2 in which the fabric is unrolled from a feed roll 22 and is passed between rollers 23 and 24, the roller 23 carrying knife blades
30 25 suitably oriented in relation to the axis of the roller 23 to produce conterminous zig-zag cuts in the fabric. Roller 24 serves as a backing roller and the

cut fabric is wound up on a roller 26.

The roll of cut fabric is next taken to an apparatus as shown in Figure 3 where a guillotine 27 acting against a block 28 severs the fabric, unwound from a roller 29, into preform units. If necessary a bandsaw or other cutting device may be used in place of a guillotine. The two preform units resulting from each operation of the guillotine 27 are wound up on separate cylindrical formers 30, 31 juxtaposed on a common axis at the take-up end of the apparatus of Figure 3.

The diameter of the cylindrical formers 30 is such that the cross-section of each former is approximately the same as the opening in the helmet to be manufactured. The pitch of the teeth 18 and 19 is such that when wound on the formers 30, teeth of successive layers of the fabric parts 14 and 15 are in staggered relationship. That is the teeth of the second layer of fabric overlap the gaps between the teeth of the first layer of fabric and so on, the number of layers of fabric used depending on the type of helmet to be produced. Twelve to twenty four layers are commonly used.

The rolled up layers of fabric ready for the final operation in manufacture of the preform are illustrated at 33 in Figure 4 and Figure 5 shows this final operation. The rolled up layers of fabric 33 of the fabric part 14 are placed on a tapering circular section support 34 and a dome-shaped die 35 descends on the ends of the teeth 18, bends them inwardly towards one another and

- 5 -

welds them together in the crown region using a radio frequency welding technique to form a preform 36.

A small crown 39, or several such crowns, which may be circular in shape, may be located on top of or beneath the dome formed by the closing teeth or can be interleaved with them and may be welded to them in the same procedure. Other reinforcement may be provided in the same region of the dome as an alternative to or in addition to one or more crowns, for example one or more annular shaped reinforcements may be used.

Finally, to manufacture a composite helmet from the preform 36, the preform is placed on the dome-shaped male part 37 of a mould and is subjected to heat and pressure after the female part 38 of the mould has been closed down over the male part 37.

The helmet shape thus produced requires trimming and attachment of fittings for example internal padding.

The reinforcing fabric 10 used for the blanks and for the crown reinforcement 39 may be a woven fabric made of polyaramid fibre or a ballistic quality nylon fibre.

The resin used for impregnation of the reinforcing fabric could be a phenolic resin (e.g. a 50:50 solids blend of phenol-formaldehyde and polyvinylbutyral resins), a polyester resin or a thermoplastic resin.

CLAIMS

1. A method of making a blank for a preform for a composite helmet reinforced with cut fabric pieces, characterised in that a length of reinforcing fabric (10) is cut along a zig-zag line (13) so that the length
5 of fabric is dividable along the cutting line into two parts (14, 15), each part comprising an uncut longitudinally extending base portion (16, 17), and a series of teeth (18, 19) projecting from the said uncut base portion along one edge thereof.
- 10 2. A method as claimed in claim 1, characterised in that the fabric is impregnated with a resin before cutting the length of fabric (10).
- 15 3. A method as claimed in claim 1, characterised in that the fabric is impregnated with a resin after cutting the length of fabric (10).
- 20 4. A method as claimed in claim 1, 2 or 3, characterised in that the two parts (14, 15) cut from the length of reinforcing fabric (10) are separately wound onto two juxtaposed cylindrical formers (30,31) having a common
25 axis and each having a diameter approximately the same size as the opening in a helmet to be manufactured, so that the uncut base portion (16) of one part (14) is wound on one of the cylindrical formers (30) and the uncut base portion (17) of the other part (15) is wound
30 on the other cylindrical former (31), and wherein the pitch of the teeth (18, 19) in each part (14, 15) is such that when each part (14, 15) is wound on its respective cylindrical former (30, 31), teeth (18, 19) of successive layers of fabric of each part are in staggered relationship.
5. A method as claimed in claim 1, 2, 3 or 4, characterised in that the cutting of the length of fabric

- 7 -

(10) is carried out by a die cutter through which the length of fabric (10) is moved intermittently.

6. A method as claimed in claim 1, 2, 3 or 4, characterised in that the cutting of the length of fabric (10) is carried out by a rotary cutter (23, 24) through which the length of fabric (10) is moved continuously.

7. A blank for a preform for a composite helmet, reinforced with cut fabric pieces, characterised in that the blank comprises a part (14, 15) of a length of reinforcing fabric (10), said part (14, 15) having a longitudinally extending base portion (16, 17) to define one straight-edge (11, 12) of the blank and a series of teeth (18, 19) projecting away from the base portion (16, 17) to define the other edge of the blank.

8. A blank as claimed in claim 7, characterised in that the reinforcing fabric (10) is impregnated with resin.

9. A blank as claimed in claim 7 or 8, characterised in that the pitch of the teeth (18, 19) in relation to the size of a helmet to be manufactured is such that when the blank is wound on a former (30, 31) of that size, the teeth (18, 19) are in staggered relationship.

10. A method of making a preform for a composite helmet reinforced with cut fabric pieces, characterised by the steps of winding a blank (14, 15), comprising a length of reinforcing fabric (10) having a longitudinally extending base portion (16, 17) defining one edge (11, 12) of the blank, and a series of teeth (18, 19) projecting from the base portion to define the other edge of the blank, onto a former (30, 31) to produce a plurality of layers of fabric with staggered teeth in successive layers, and shaping the preform (36) by bending the teeth

inwardly towards one another.

11. A method of making a preform as claimed in claim 10, characterised in that the preform (36) is shaped by bending the teeth (18, 19) inwardly so that teeth
5 of the same layer meet or overlap and the inwardly bent teeth are secured to one another.

12. A method of making a preform as claimed in claim 11, characterised in that the preform (36) is further reinforced by introduction of at least one further
10 piece (39) of reinforcing fabric in the region of the crown.

13. A method of making a composite helmet reinforced with cut fabric pieces, characterised in that a resin-impregnated preform (36) obtainable by the method of
15 claim 10, 11 or 12 is subjected to heat and pressure.

14. A preform obtainable by the method claimed in claim 10, 11 or 12.

15. A helmet obtainable by the method claimed in claim 13.

20 16. A blank obtainable by the method claimed in any one of claims 1 to 6.
